Assignment 9

Bug ID: AX-001

Description of the Issue:
The user profile page fails to load account information because the backend API is unable to retrieve user data from the SQL database. When the profile page attempts to fetch user details, the database query does not return the required data, causing the application to display an error message instead of the user profile.

Steps to Reproduce:

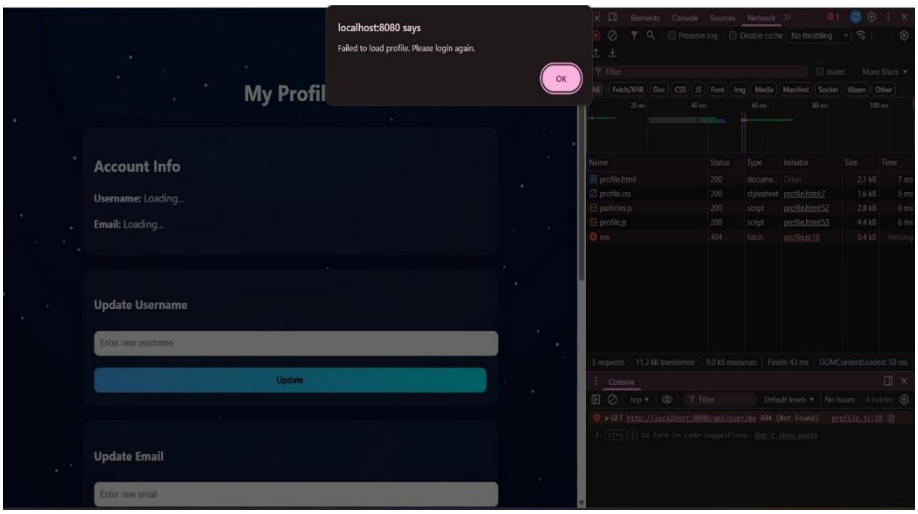
1. Login to the AssistX application using valid credentials.
2. Navigate to the Profile page.
3. The frontend sends a request to the backend API to retrieve user profile information.
4. The API attempts to fetch the data from the SQL database.

Expected Result:
The profile page should successfully retrieve and display the user's information such as username and email address.

Actual Result:
The system fails to retrieve the user information from the database and displays the message:
“Failed to load profile. Please login again.”

Severity Level:
High

Suggested Fix:
Verify that the backend API correctly connects to the SQL database and retrieves the authenticated user’s data. Ensure the database query uses the correct user identifier and returns the required fields to the frontend.



Bug ID: AX-002

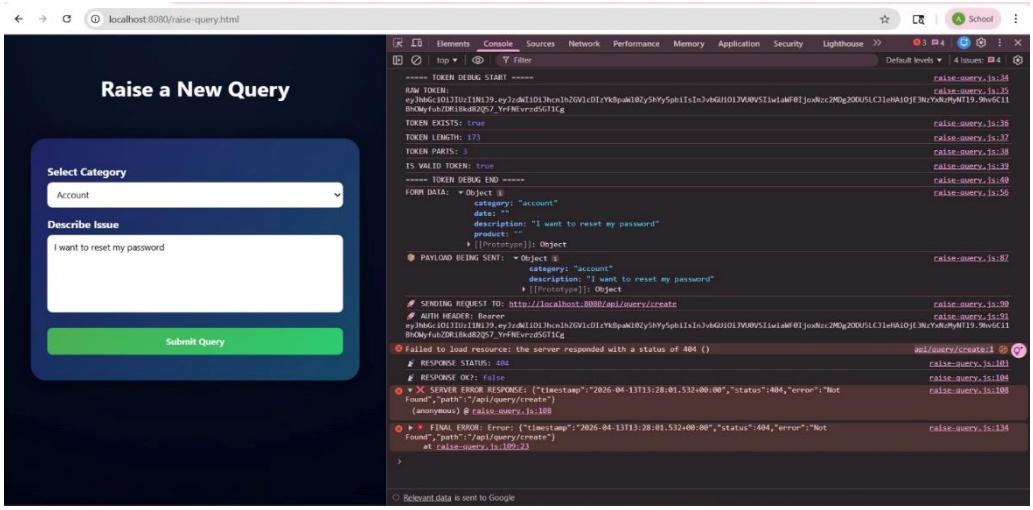
Description of the Issue:
The Raise Query API endpoint returns a 404 Not Found error even though the endpoint exists in the backend code. The issue occurs because the JWT authentication token overrides the OAuth token, corrupting OAuth-related fields such as the username. Since the username field is validated against the database before creating a query, the system fails to locate the correct user and returns a 404 error.

Steps to Reproduce:

1. Login to the AssistX application.
2. Navigate to the Raise Query page.
3. Select a category and enter a description for the issue.
4. Click the Submit Query button.
5. Observe the network request made to the backend endpoint for creating a query.

Expected Result:
The API should validate the user authentication token and successfully create a new query entry in the database.

Actual Result:
The API returns a 404 Not Found error even though the endpoint exists. This occurs because the JWT token overrides the OAuth token and corrupts the authentication fields required to identify the user.



Severity Level:
High

Suggested Fix:
Update the authentication logic so that JWT tokens do not override OAuth token data. Ensure proper validation of authentication tokens and correct mapping of user fields such as username before performing database checks.

Bug ID: AX-003

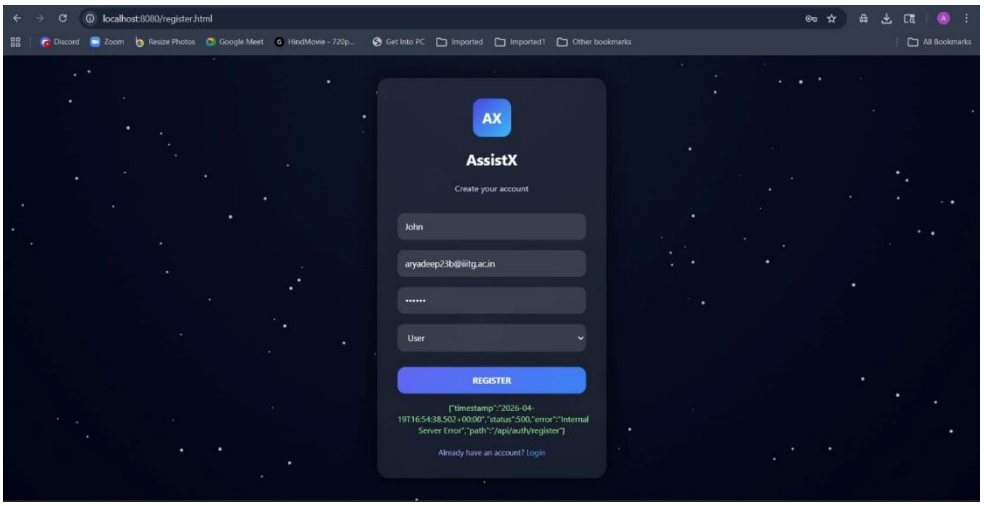
Description of the Issue:
During user registration, if a user attempts to register with an email address that already exists in the system, the frontend fails to display the correct error message. The issue occurs due to an error in the frontend JavaScript file responsible for handling API responses.

Steps to Reproduce:

1. Open the registration page of the AssistX application.
2. Enter a username and an email address that already exists in the database.
3. Enter a password and select the user role.
4. Click the Register button.

Expected Result:
The system should display a clear error message indicating that the email address already exists and the user should use a different email.

Actual Result:
The frontend fails to display the appropriate error message due to a JavaScript error, resulting in either no message being shown or an incorrect error response.

Severity Level:
Medium


Suggested Fix:
Update the frontend JavaScript logic to correctly handle error responses from the backend API. Ensure that duplicate email validation errors are properly captured and displayed to the user.
